# Acknowledgment

---

To my tutor, Jesús, for guiding me in this project, for trusting me to join the research group to which he belongs, for supporting me in my decision to join a doctoral program, for always seeking the best for us despite of his preferences and for his kindness.

To all those department mates who have helped me every time I have needed it and all those who have ever volunteered to help. In particular, I would like to thank Fran and Arturo for all the time they have dedicated to helping me.

To Damián, for accompanying me in the easy and difficult moments, but above all, for being my friend, and for being there unconditionally for whatever I needed.

To my classmates, who despite being a difficult year with social distancing, have been as close as ever.

To all my friends, for being such good friends.

To my entire family, for their unconditional love and support, and for their patience and understanding.

Thanks for everything

*Álvaro Calvo Matos*

# Abstract

---

This Master's Thesis has addressed problems arising from the recent increase in the applications of cooperative teams, which are the autonomy to operate over a long period of time with robustness to possible failures, and the difficulty of providing the team with cognitive capabilities to be able to operate in dynamic environments with humans.

Many of these applications are currently being executed by humans, making the activities much more expensive, time-consuming, and in some cases even dangerous. This is why there is currently a great deal of interest and effort being put into developing solutions to the problems posed, as they can mean, in addition to significant savings for companies, a drastic improvement in the safety of workers in high-risk jobs. Specifically, the application on which this work has focused is the assistance to human operators in inspection and maintenance tasks on high-voltage power lines.

The aim of the work was to develop cognitive planning techniques for coordinating fleets of quadrotors to assist human operators in inspection and maintenance tasks on high-voltage power lines. These techniques should also extend the autonomy of the system, ensure that safety requirements between drones and human workers are met, and ensure the success of the mission.

A software architecture has been proposed based on a central planner, which is in charge of planning actions over time and monitoring the status of each of the connected equipment; and the behaviour manager, distributed on board each of the UAVs, which is in charge of executing the plan assigned by the central module. The distributed module contains the minimum intelligence that ensures compliance with safety requirements, so that the rest of the intelligence can be concentrated in the centralised module. This reduces the computational load on the aerial equipment as much as possible, thus extending battery life. It has also been assumed that there is some way of recharging the battery during the mission, so that among the actions available to the centralised module for planning, there is also the option of recharging. To carry out the planning, a cost has been defined, which is calculated for each task. Respecting, among other things, the priorities of the tasks and their order of arrival, each task is assigned to the Unmanned Aerial Vehicle (UAV) that costs the least to execute. On the other hand, to control the behaviour of the drones and ensure the safety of the aerial equipment, a behaviour tree has been implemented.

As a result, it has been possible to develop a software architecture capable of dynamically planning missions while ensuring the safety of the equipment involved. Thanks to the planning, a better coordination of the UAVs is achieved and therefore, a better use of the battery, thus extending the autonomy of the equipment. The core module provides a good base that can be easily adapted to other projects involving multi-UAV teams and from which more complex planners can be developed in the future. At the same time, the design of the distributed modules, thanks to the use of behaviour trees, allows for easy reuse and modification. Compared to the typical way of implementing such modules, which involves the creation of complex finite state machines that are difficult for a human

to read, reuse and extend, the use of behaviour trees is a great improvement and will allow the creation of increasingly complex behaviours.
